

Heuristic Analysis

This work presents 3 heuristics for achieving better performance than the ID_Improved agent. Each one increases the complexity in terms of computation and implementation. Let's analyze each one:

Center moves

Intuition

The more moves at the center this player has, the better the outcome of the game will be.

Implementation

This function simply subtracts the opponent's center moves from the player's center moves. Center moves are defined as the inner 3x3 rectangle of the board.

Center moves with blank spaces

Intuition

Same as the above but we scale according to the available blank squares.

Implementation

Call `center_moves()` and divide the result by the number of blank squares.

Uber heuristic

Intuition

The ultimate heuristic (as the name suggests :))! Rewards the player more when he has more available moves and center moves as opposed to his opponent. Finally, the result is scaled by the player's remaining moves.

Implementation

The heuristic implements the following formula:

$$Score = \frac{(P_{moves} + P_{center\ moves}) - (O_{moves} + O_{center\ moves}) - B}{B + P_{moves} - O_{moves}}$$

where P is the player, O is the opponent and B is the number of blank squares.
